1 Introduction

- Context: The big problem
- Problem statement: The small problem
- Methodology / Strategy
- Structure

Notes:

- Huge amounts of text, which can provide insight about stuff
- Automatic tools can provide assistance for humans to process all the text
- This generally means filtering the original text corpus or otherwise reducing amount of information the information that has to be processed by humans
- Filtering introduces a bias
- Especially for scientific purposes it is relevant to mitigate bias or at least understand what bias has been introduced (to make it transparent)
- Semantic Hypergraphs can be a valuable tool for that because...

Human life in times of widespread use of the internet and smartphones is most certainly more than ever interspersed with text-based communication...

A Semantic Hypergraphd (**menezes_semantic_2021**) is a form of representation for Natural Language (NL) and therefore knowledge. *NL* sentences can be modelled as a recursive hypergraph which can be represented in a formal language. The framework allows to specify semantic patterns in this formal language which can be matched against an existing *SH*.

The aim of the SH framework is to provide a *open* and *adaptive* framework to analyse text corpora, especially in the domain of computational social science (CSS) (**lazer2009computational**). The framework is *open* in the sense that it's representation formalism is inspectable and intelligible by humans and that the pattern matching follows explicit rules. The framework is adaptive in the sense that the parsing is based on adaptive subsystems (ML-based) and therefore allows for an error-tolerant parsing from *NL* to *SH* in regards to grammatical and syntactical correctness (???).

2 Fundamentals and Related Work

2.1 Semantic Hypergraph

2.1.1 Structure

Edge

Edge Content

Root edge / Sequencen (i use the term "sequence root edge")

2.1.2 Syntax

wildcard operator

Variables

Square bracket notation

Differences between the formal notation and the notation used in the implementation (or should this be contained in the implementation chapter?)

2.2 Semantic Similarity

2.2.1 Different Similarity Measures

String Similarity

Levenshtein distance, etc..

Lexical Similarity

tf-idf, etc.?

2.2.2 Types of Semantic Similarity

Lexical Databases

WordNet and alike (not the scope of this work)

2.3 Embedding-based Similarity

2.3.1 Embedding Types

Fixed Word Embeddings

Contextual Embeddings

2.3.2 Distance Measures

Mean reference vector vs. pairwise distance

3 Problem Statement

CSS researches may typically be interested in retrieving statements of specific kind from a text corpus, such as expressions of sentiment of an actor towards some entity or expressions of conflicts between different actors. One approach for performing the retrieval would be to use a system which allows to specify some form of pattern which abstractly represents the statements they are trying to capture. This requires the definition of some form of formal pattern language¹ and possibly the prior transformation of the text corpus into some form of structured format to match against. Another approach is to use a system, which accepts example statements concretely representing the statements that are desired to be retrieved. Those systems may require a large number of positive and negative examples to be able to perform the retrieval. The two types of retrieval systems described here are in tendency situated in the realms of symbolic IR/IE and probabilistic ML/DL respectively.

The SH framework is more situated in the former symbolic realm. In SH text is represented in the form of *hyperedges* (in the following also referred to as *edges* only). These edges are either atomic or they consist of edges themselves, which essentially accounts for the recursive character of the SH. Each edge has a specific *type* from a set of eight different types of which the most trivial two types are probably *concept* (C) and *predicate* (P).

Users of the SH framework (e.g. CSS researchers) can define patterns in the SH formalism to match against a text corpus (e.g. a collection of news articles) that has previously been parsed as an SH. These patterns may among other things specify the structure of the edges that should match it as well as their type (and the types of possible sub-edges). Additionally the actual words that should match need to be specified i.e. the content to match against, if the structure of an edge matches the pattern. There are additional operators in the pattern language such as the wildcard operator *, which can be used e.g. to match every atomic edge edge of a specific type and therefore discard content.

To better illustrate the problem Hyperedge 2 and Hyperedge 1 demonstrate how NL sentences are parsed to SH based on this simplified introduction the the SH representation.

(likes/P ann/C apples/C)

Hyperedge 1: SH representation for the sentence "Ann likes apples"

(likes/P ann/C bananas/C)

Hyperedge 2: SH representation for the sentence "Ann likes bananas"

Hyperedge 1 and Hyperedge 2 both follow the same structure, but differ in the content of the last sub-edge. Both edges are hence matched by Pattern 1, which does not specify content for this sub-edge. The SH pattern language also allows to define a pattern that matches both Hyperedge 1 and Hyperedge 2 via a list of words as in Pattern 2. However

¹The *Google Search* query language can be seen as a simple example of such a pattern language, albeit with a different use case focus: <https://support.google.com/websearch/answer/2466433?hl=en>

is not possible to define a pattern that matches based on some form of *Semantic Relatedness* (SR) or *Semantic Similarity* (SS) (Harispe et al. 2015) regarding content. Referring to the example above this means using the SH framework it is not directly possible to retrieve every sentence that declares that "Ann likes *some kind of fruit*" or that "Ann likes *fruits similar to apples*". This former would require to provide a comprehensive list of every fruit while the latter would require the user to specify all fruits he deems similar to apples.

(likes/P Ann/C */C)

Pattern 1: "Ann-likes-something" pattern

(likes/P ann/C [apples, bananas]/C)

Pattern 2: "Ann likes apples or bananas" pattern

Utilizing some form of SR/SS regarding to edge content for the matching step would allow users to define more generalising patterns. There exists a great variety of approaches for determining the SR/SS of text, which can generally be divided into *Corpus-based Measures* and *Knowledge-based measures* (Harispe et al. 2015, Section 1.3.2). The latter approaches may generally provide the explicitness in the measurement determination that is desired by CSS researchers. However among the former recent ML-based and especially DL-based approaches have been outperforming most other approaches (Chandrasekaran and Mago 2021). They generally rely on computing a vector space representation (or embedding) of texts which can then be used to calculate their similarity and will therefore be referred to as *Neural Embedding-based Semantic Similarity* (NESS) measures in the following.

Word semantics generally depend on textual context and hence does the SS between words (Harispe et al. 2015, Section 2.2.3). Incorporating contextuality when extending the SH pattern matching process by SS therefore poses a central challenge. Context-dependent SS would allow to specify matching edge content beyond isolated word semantics, although this may not always be desirable or necessary as in the example above.

As illustrated earlier, NESS measures principally do not provide the explicitness that is inherent to the pattern matching process of the SH framework. In the sense of the adaptive-open classification described above an integration of NESS would mean a shift from openness to adaptivity in this regard. While the SH framework generally can be situated in the realm of symbolic approaches, this integration would build a bridge between it and the realm of probabilistic approaches.

3.1 Research Questions

Based on the problem statement outlined above, we pose the following research questions:

3.1.1 Primary Question

R Can neural embedding-based semantic similarity regarding edge content be integrated into the pattern matching of the Semantic Hypergraph framework to allow for more generalising patterns while providing control over the adaptiveness and therefore loss of explicitness in the matching process?

3.1.2 Secondary Questions

R.1 What neural embeddings model would be the most suitable for accurately assessing semantic similarity within the Semantic Hypergraph pattern matching process while effectively addressing the challenges posed by contextuality?

R.2 To what extent does incorporating neural embedding-based semantic similarity improve the generalization performance (recall) and how does it impact precision when matching a pattern against a set of known desired matching results?

R.3 How can adaptiveness and explicitness of the matching process be effectively and transparently balanced and controlled?

4 Solution Approach

In this chapter we present the approach that was developed to answer the research questions (see section 3.1). Therefore trying to provide a solution to the problem of extending the SH framework by Neural Embedding-based Semantic Similarity Matching, which is described in chapter 3 where the relevancy of this problem for has also been derived.

The system is described here will in the following be referred to as *Neural Embedding-based Semantic Similarity extended Semantic Hypergraph Pattern Matching* or:

NESS-SHPM aka *NESSeSHyPaM*

4.1 Integration into the Pattern Matching Process

4.1.1 semsim Functional Pattern

pattern works only for atoms

4.1.2 Sub-pattern Similarity Thresholds

4.2 Fixed Word Embedding-based Matching

word2vec via gensim

discussion about using transformer models for single word embeddings?

single-word and multi-word reference

Square bracket notation

4.3 Contextual Embedding-based Matching

i generally like your idea of contrasting the discrete and continuous space as it allows to point out that there can't be one single point, also for a set of words which represents the meaning, but rather some subspace depending on the specific context. Regarding the point of the semantic entities in continuous space being either word- or phrase based, the important difference is, that in case of semsim with context we do not compare the embedding representation of the phrases themselves. rather the sentences/phrases influence the embedding representations of the word (or maybe phrases). I tend to see this a bit like a blurring algo. The meaning of each token starts bleeding into its neighbours.

4.3.1 Context References

4.3.2 Token Mapping

4.4 Similarity Threshold Control

4.4.1 Breakpoint Discovery

detect change points in number of matches
see <https://github.com/deepcharles/ruptures>

half-max point and quarter/three-quarter points (percentiles, not quantiles) fit function and search for inflection as well as maximum derivative points, problematic in cases with less continuous change in number of matches.

how to approach this for practical applications?

5 Implementation

5.1 Relevant external Software Libraries used

Here list libs and models to be referenced later.

Word2Vec Gensim SentenceTransformers Transformers SpaCy

5.2 Modules newly added to the SH Framework

5.3 Modifications of the SH Pattern Matching

5.4 Modifications to the Hypergraph database

6 Evaluation and Results

In this chapter the conceived concept (see chapter 4) and specific implementation (see chapter 5) of the NESS-SHPM system is being evaluated to answer the research question(s) posed in section 3.1. Therefore a case study is conducted to evaluate the system for a specific use case. In this case study quantitative results as well as qualitative examinations of the behaviour of NESS-SHPM are conducted. The quantitative results display the systems performance using metrics which are established for retrieval and classification tasks. The qualitative results exemplary showcase detailed aspects of the systems behaviour in the given use case.

6.1 Case Study: Conflicts

The conflicts case study follows the approach presented in (Menezes and Roth 2021, p. 22) where expressions of conflict are extracted from a given SH using a single pattern. In their work they build upon the information extracted by the pattern (e.g. the two conflict parties) to conduct further analysis, which are not in the scope of this work. Here the evaluation is limited to the task of classifying whether the content of a given edge in the SH is an expression of conflict or not. Or framed differently the task is to retrieve exactly all those edges whose content is an expression of conflict.

should I explain why specifically the conflicts and not some other case study (i.e. dataset) -> because there was none... but then I need to show why there was none and what are the criteria for a case study to be suitable to evaluate the system

6.1.1 Reddit Worldnews Corpus

The corpus from which those expressions of conflict are retrieved consists of news titles that were shared on the social media platform *Reddit*. Specifically all titles shared between January 1st, 2013 and August 1st, 2017 on *r/worldnews*¹, which is described as: “A place for major news from around the world, excluding US-internal news.” This corpus will in the following be referred to as the *Worldnews-Corpus* and contains 479,384 news headers.

Each of these headers is comprised of a single sentence and is represented as a sequence root edge in the corresponding SH. The SH that is constructed from this corpus will in the following be referred to as the *Worldnews-SH*.

examples

¹<http://reddit.com/r/worldnews>

6.1.2 Original Conflict Pattern

Pattern 3 is used in (Menezes and Roth 2021, p. 22) to extract conflicts between two parties SOURCE and TARGET, potentially regarding some TOPIC:

$$(\text{ PRED/P.so,x SOURCE/C TARGET/C [against,for,of,over]/T TOPIC/[RS] }) \wedge \\ (\text{ lemma/J >PRED/P [accuse,arrest,clash,condemn,kill,slam,warn]/P })$$

Pattern 3: Original conflict pattern

Matching this pattern against the Worldnews-SH yields XYZ matches.

add exam-
ples

6.1.3 SemSim Conflict Patterns

The part of Pattern 3 that mostly defines its retrieval performance is the list of predicates. This list has been manually constructed by (Menezes and Roth 2021) by investigating the Worldnews-Corpus. To evaluate the NESS-SHPH, this pattern will be modified to include the semsim functional pattern instead of the lemma functional pattern and the fixed word list. The general form of such a pattern is shown by Pattern 4. This means only the matching of the predicate will be subject NESS, which allows to isolate the effects of the integration of NESS in the pattern matching process.

$$(\text{ PRED/P.so,x SOURCE/C TARGET/C [against,for,of,over]/T TOPIC/[RS] }) \wedge \\ (\text{ semsim/J PRED/P .../P })$$

Pattern 4: Original conflict pattern

6.1.4 Conflict Dataset

To conduct an evaluation which assesses the retrieval performance of the NESS-SHPM system it is necessary to have a dataset of edges with labels that state whether an edge is an statement of conflict or not. Since such a dataset did not exists it needs to be constructed. In the following the characteristics and the creation process of the dataset which was used for the evaluation in this case study will be shown.

Definition of Conflict

Firstly an expression of conflict in the context of this case study is defined as a sentence which bears the following characteristics:

There is a conflict between two explicitly named actors, wherever these actors are mentioned in the sentence; whereby a conflict is defined as antagonizing desired outcomes.

Creation Process

The set of edges that can be retrieved by a pattern following the form of Pattern 4 is restricted the general structure of this pattern. That means every set of matches for a pattern of this form will be a subset of the matches of the pattern which uses a wildcard operator to match the predicate (see Pattern 5). The results of matching this pattern against the Worldnews-SH are therefore used as the basis set of edges from which the conflict dataset is constructed instead of the entirety of all its sequence root edges.

$$(\text{ PRED/P.so,x SOURCE/C TARGET/C [against,for,of,over]/T TOPIC/[RS] }) \wedge \\ (\text{ PRED/P */P })$$

Pattern 5: Wildcard predicate pattern

Sampling sampling the dataset from the pattern matching results -> lemma-based binning

Labeling -> 50 edges labeled by everyone, then asses disagreements and refine understanding of conflict.

7 Conclusion

8 Future Work

8.1 Implementation Improvements

implemnt multiprocessing, i.e. server process for both hypergraph and semsim matchers.
other option would be to leverage python shared memory capabilities but is likely to be less stable and has less scaling potential

8.2 Further Evaluations
